Adjoints of ideals

Reinhold H"ubl and Irena Swanson*

Abstract. We characterize ideals whose adjoints are determined by their Rees valuations. We generalize the notion of a regular system of parameters, and prove that for ideals generated by monomials in such elements, the integral closure and adjoints are generated by monomials. We prove that the adjoints of such ideals and of all ideals in two-dimensional regular local rings are determined by their Rees valuations. We prove special cases of subadditivity of adjoints.

Adjoints and multiplier ideals have recently emerged as a fundamental tool in commutative algebra and algebraic geometry. In characteristic 0 they may be defined using resolution of singularities. In positive prime characteristic $p$, Hara and Yoshida [4] introduced the analog of multiplier ideals as generalized test ideals for a tight closure theory. In all characteristics, even mixed, Lipman gave the following definition:

Definition 0.1: Let $R$ be a regular domain, $I$ an ideal in $R$. The adjoint $\text{adj} I$ of $I$ is defined as follows:

$$\text{adj} I = \bigcap_v \{ r \in R \mid v(r) \geq v(I) - v(J_{R_v}/R) \},$$

where the intersection varies over all valuations $v$ on the field of fractions $K$ of $R$ that are non-negative on $R$ and for which the corresponding valuation ring $R_v$ is a localization of a finitely generated $R$-algebra. The symbol $J_{R_v}/R$ denotes the Jacobian ideal of $R_v$ over $R$.

By the assumption on $v$, each valuation in the definition of $\text{adj} I$ is Noetherian.

Many valuations $v$ have the same valuation ring $R_v$; any two such valuations are positive real multiples of each other, and are called equivalent. In the definition of $\text{adj} I$ above, one need only use one $v$ from each equivalence class. In the sequel, we will always

Key words and phrases. Adjoint ideal, multiplier ideal, regular ring, Rees valuation.
choose normalized valuations, that is, the integer-valued valuation \( v \) such that for all \( r \in R \), \( v(r) \) equals that non-negative integer \( n \) which satisfies that \( rR_v \) equals the \( n \)th power of the maximal ideal of \( R_v \).

Lipman proved that for any ideal \( I \) in \( R \) and any \( x \in R \), \( \text{adj}(xI) = x \text{adj}(I) \). In particular, \( \text{adj}(xR) = (x) \).

A crucial and very powerful property is the subadditivity of adjoints: \( \text{adj}(IJ) \subseteq \text{adj}(I) \text{adj}(J) \). This was proved in characteristic zero by Demailly, Ein and Lazarsfeld [3], and for generalized test ideals in characteristic \( p \) by Hara and Yoshida [4, Theorem 6.10]. A simpler proof in characteristic \( p \) can be found in [1, Lemma 2.10]. A version of subadditivity formula on singular varieties was proved by Takagi in [21]. But subadditivity of adjoints is unknown in general. We prove it for generalized monomial ideals in Section 4, and for ideals in two-dimensional regular domains in Section 5. The case of subadditivity of adjoints for ordinary monomial ideals can be deduced from Howald’s work [5] using toric resolutions, and the two-dimensional case has been proved by Takagi and Watanabe [22] using multiplier ideals. The case for generalized monomial ideals proved here is new.

An aspect of proving subadditivity and computability of adjoints is whether there are only finitely many valuations \( v_1, \ldots, v_m \) such that for all \( n \),

\[
\text{adj}(I^n) = \bigcap_{i=1}^{m} \{ r \in R \mid v_i(r) \geq v_i(I^n) - v_i(J_{R_v}/R) \}.
\]

We prove in Sections 4 that Rees valuations suffice for the generalized monomial ideals. We also give an example (the first example in Section 5) showing that Rees valuations do not suffice in general. In Section 5 we give a general criterion for when the adjoint of an ideal is determined by its Rees valuations. A corollary is that Rees valuations suffice for ideals in two-dimensional regular domains. The first three sections develop the background on generalized monomial ideals.

We refer the reader to the article by Smith and Thompson [19] and to Järvilehto’s thesis [8] for results on what divisors (i.e., valuations) are needed to compute the multiplier
ideals with rational coefficients. In general, Rees valuations do not suffice there, even in dimension two.

1. Generalized regular system of parameters

Definition 1.1: Let $R$ be a regular domain. Elements $x_1, \ldots, x_d$ in $R$ are called a generalized regular system of parameters if $x_1, \ldots, x_d$ is a permutable regular sequence in $R$ such that for every $i_1, \ldots, i_s \in \{1, \ldots, d\}$, $R/(x_{i_1}, \ldots, x_{i_s})$ is a regular domain.

Remark: Any part of a generalized regular system of parameters is again a generalized regular system of parameters.

For example, when $R$ is regular local, an arbitrary regular system of parameters (or a part thereof) is a generalized regular system of parameters; or if $R$ is a polynomial ring over a field, the variables are a generalized regular system of parameters.

Let $p$ be any prime ideal containing the generalized regular system of parameters $x_1, \ldots, x_d$. As $R/(x_1, \ldots, x_d)$ is regular, so is $R_p/(x_1, \ldots, x_d)_p$, whence $x_1, \ldots, x_d$ is part of a (usual) regular system of parameters in $R_p$.

Lemma 1.2: Let $R$ be a regular domain and $x_1, \ldots, x_d$ a generalized regular system of parameters. Then for any normalized valuation $v$ as in the definition of adjoints, $v(J_{R_v}/R) \geq v(x_1 \cdots x_d) - 1$.

Proof: By possibly taking a subset of the $x_i$, without loss of generality all $v(x_i)$ are positive. Let $p$ be the contraction of the maximal ideal of $R_v$ to $R$. After localizing at $p$, $x_1, x_2, \ldots, x_d$ are a part of a regular system of parameters (see comment above the lemma). We may possibly extend the $x_i$ to a full regular system of parameters, so we may assume that $p = (x_1, \ldots, x_d)$ is the unique maximal ideal in $R$. We may also assume that $v(x_1) \geq v(x_2) \geq \cdots \geq v(x_d) \geq 1$.

If $d = 0$, the lemma holds trivially. If $d = 1$, then $v$ is the $p$-adic valuation, in which
case $R_v = R$, $J_{R_v}/R = R$. As $v$ is normalized, $v(x_1) = 1$, and the lemma holds again.

Now let $d > 1$ and let $S = R[\frac{x_1}{x_d}, \ldots, \frac{x_{d-1}}{x_d}]$. Then $S$ is a regular ring contained in $R_v$, and $\frac{x_1}{x_d}, \ldots, \frac{x_{d-1}}{x_d}, x_d$ are a generalized regular system of parameters in $S$. Clearly $J_S/R$ equals $x_d^{d-1}S$. By induction on $\sum v(x_i)$ we conclude that $v(J_{R_v}/S) \geq v(\frac{x_1}{x_d} \cdots \frac{x_{d-1}}{x_d} x_d) - 1$, so that by Lipman and Sathaye [14, page 201], $v(J_{R_v}/R) = v(J_S/R) + v(J_{R_v}/S) \geq v(x_d^{d-1}) + v(\frac{x_1}{x_d} \cdots \frac{x_{d-1}}{x_d} x_d) - 1 = v(x_1 \cdots x_d) - 1$.

Though in general not as nicely behaved as variables in a polynomial or power series ring, generalized regular systems of parameters come close to them in many aspects. One

interesting property is the following.

**Proposition 1.3:** Let $R$ be a regular domain and let $x_1, \ldots, x_d$ be a generalized regular system of parameters of $R$. Furthermore let $s \leq d$, $p = (x_1, \ldots, x_s)$ and let $f$ be a non-zero element of $R$. Then there exist monomials $m_1, \ldots, m_t$ in $x_1, \ldots, x_s$ and elements $h, g_1, \ldots, g_t \in R \setminus p$ such that

$$h \cdot f = \sum_{i=1}^t g_i \cdot m_i.$$

**Proof:** Clearly we may assume that $R$ is local with maximal ideal $p$, and we then prove the proposition with $h = 1$. First we reduce to the case of complete local rings: Let $\hat{R}$ be the completion of $R$, and note that $x_1, \ldots, x_s$ is a regular system of parameters of $\hat{R}$.

Suppose we know the result for $\hat{R}$ and $x_1, \ldots, x_s \in \hat{R}$. Write $f = \sum_{i=1}^t h_i m_i$ for some $h_i \in \hat{R}$, $h_i \notin p$. Clearly we may assume that none of the monomials is a multiple of another one. Let $I = (m_1, \ldots, m_t) \subseteq R$. As $f \in I \hat{R} \cap R = I$ by faithful flatness, we may write $f = \sum_{i=1}^t g_i m_i$ with $g_i \in R$, and in $\hat{R}$ we get $\sum_{i=1}^t (g_i - h_i) m_i = 0$ hence we conclude from [9], §5, that $g_i - h_i \in p \hat{R}$, implying that $g_i \notin p$. Thus it suffices to prove the proposition in the case $R$ is complete local with maximal ideal $p = (x_1, \ldots, x_s)$.

Assume now that $R$ is complete and let $f \in R$. Assume $f \in p^{n_1} \setminus p^{n_1+1}$. Then we may write

$$f = \sum_{i=1}^{t_1} a_i m_{1i} + f_2.$$
with some (unique) monomials $m_{i_1}$ of degree $n_1$ in $x_1, \ldots, x_s$ and some $a_{i_1} \notin p$ (unique mod $p$) and with some $f_2 \in p^{n_1+1}$. Let $M_1 = (m_{i_1}, \ldots, m_{i_t})$. If $f_2 = 0$ we are done, otherwise we write

$$f_2 = \sum_{i=1}^{t_2} a_{2i}m_{2i} + f_3$$

with some $a_{2i} \notin p$, some monomials $m_{2i}$ of degree $n_2$ in $x_1, \ldots, x_s$, and some $f_3 \in p^{n_2+1}$. Set $M_2 = M_1 + (m_{21}, \ldots, m_{2t_2})$ and continue. In this way we get an ascending chain $M_1 \subseteq M_2 \subseteq \cdots$ of monomial ideals, which must stabilize eventually, $M_\rho = M_{\rho+1} = \cdots = M_\infty$.

Let

$$M_\infty = (m_1, \ldots, m_t),$$

with each $m_i$ a monomial of degree $d_i$ in $x_1, \ldots, x_s$. We may assume that none of these monomials divides any of the other ones and that all $m_i$ appear in a presentation of some $f_j$ as above. Then in each step above we may write

$$f_l = \sum_{i=1}^t n_{li}m_i + f_{l+1}$$

with $n_{li} \in p^{n_l-d_i}$, and where furthermore if $l$ is the smallest integer such that $m_i$ appears with a non-trivial coefficient in the expansion of $f_l$, we have $n_{li} \notin p$. Hence

$$f = \sum c_im_i + f_{l+1}$$

with some $c_i \notin p$ (or $c_l = 0$), and with $c_{l+1,i} - c_l \in p^{n_l-d_i}$ (and $f_{l+1} \in p^{n_{l+1}+1}$). As $R$ is complete, this converges, and we get

$$f = \sum c_i m_i$$

with some $c_i \notin p$.  \qed
2. Integral closures of (general) monomial ideals

Monomial ideals typically denote ideals in a polynomial ring or in a power series ring over a field that are generated by monomials in the variables. Such ideals have many good properties, and in particular, their integral closures and multiplier ideals are known to be monomial as well. The just stated result on multiplier ideals for the standard monomial ideals is due to Howald [5]. In this section we consider generalized monomial ideals and present their integral closures. For alternate proofs on the integral closure of generalized monomial ideals see Kiyek and Stückrad [10].

We define monomial ideals more generally:

**Definition 2.1:** Let $R$ be a regular domain, and let $x_1, \ldots, x_d$ in $R$ be a generalized regular system of parameters. By a monomial ideal (in $x_1, \ldots, x_d$) we mean an ideal in $R$ generated by monomials in $x_1, \ldots, x_d$.

As in the usual monomial ideal case, we can define the Newton polyhedron:

**Definition 2.2:** Let $R, x_1, \ldots, x_d$ be as above, and let $I$ be an ideal generated by monomials $x^{a_1}, \ldots, x^{a_s}$. Then the Newton polyhedron of $I$ (relative to $x_1, \ldots, x_d$) is the set $NP(I) = \{ \underline{e} \in \mathbb{Q}^d_\geq \mid \underline{e} \geq \Sigma c_i a_i, \text{ for some } c_i \in \mathbb{Q}_\geq, \Sigma c_i = 1 \}$.

$NP(I)$ is an unbounded closed convex set in $\mathbb{Q}^d_\geq$. We denote the interior of $NP(I)$ as $NP^\circ(I)$.

**Theorem 2.3:** Let $R$ be a regular domain and $x_1, \ldots, x_d$ a generalized regular system of parameters. Let $I$ be an ideal generated by monomials in $x_1, \ldots, x_d$. The integral closure $I^n$ of $I^n$ equals

$I^n = \{ x^{\underline{e}} \mid \underline{e} \in n \cdot NP(I) \cap \mathbb{N}^d \}$,

so it is generated by monomials.

**Proof:** As $NP(I^n) = n \cdot NP(I)$, we may assume that $n = 1$. Write $I = (x^{a_1}, \ldots, x^{a_s})$. Let $\alpha = x^{\underline{e}}$ be such that $\underline{e} \in NP(I) \cap \mathbb{N}^d$. Then there exist $c_1, \ldots, c_s \in \mathbb{Q}_\geq$ such that $\Sigma c_i = 1$...
Adjoints of ideals

and \( \varepsilon \geq \sum c_i a_i \) (componentwise). Write \( c_i = m_i / n \) for some \( m_i \in \mathbb{N} \) and \( n \in \mathbb{N}_{>0} \). Then

\[
\alpha^n = x_1^{n_1 a_1} \cdots x_d^{n_d a_d} (x_1^{a_1})^{m_1} \cdots (x_s^{a_s})^{m_s} \in I^{m_1 + \cdots + m_s} = \mathcal{I}^n,
\]

so that \( \alpha \in \mathcal{I} \). It remains to prove the other inclusion.

Let \( S \) be the set of hyperplanes that bound \( \text{NP}(I) \) and are not coordinate hyperplanes. For each \( H \in S \), if an equation for \( H \) is \( h_1 X_1 + \cdots + h_d X_d = h \) with \( h_i \in \mathbb{N} \) and \( h \in \mathbb{N}_{>0} \), define \( \mathcal{I}_H = (x \mid e \in \mathbb{N}^d, \sum_i h_i e_i \geq h) \). Clearly \( \mathcal{I} \subseteq \mathcal{I}_H \), \( \text{NP}(\mathcal{I}_H) \subseteq \{ e \in \mathbb{Q}^d_{\geq 0} : \sum h_i e_i \geq h \} \), and \( \text{NP}(\mathcal{I}_H) \cap \mathbb{N}^d = \{ e \in \mathbb{Q}^d_{\geq 0} : \sum h_i e_i \geq h \} \cap \mathbb{N}^d \). Suppose that the theorem is known for the (generalized) monomial ideals \( \mathcal{I}_H \). Then

\[
\mathcal{I} \subseteq \bigcap_{H \in S} \mathcal{I}_H \subseteq \bigcap_{H \in S} (\{ x \mid e \in \mathbb{N}^d \text{ and } \sum h_i e_i \geq h \text{ if } H \text{ is defined by } \sum_i h_i X_i = h \})
\]

Thus it suffices to prove the theorem for \( \mathcal{I}_H \). As before, let \( \sum_i h_i X_i = h \) define \( H \). By possibly reindexing, we may assume that \( h, h_1, \ldots, h_t \) are positive integers and that \( h_{t+1} = \cdots = h_d = 0 \). As noted above it suffices to show

\[
\overline{T}_H = (\{ x \mid e \in \mathbb{N}^d \text{ and } \sum h_i e_i \geq h \})
\]

Let \( Y_1, \ldots, Y_t \) be variables over \( R \) and \( R' = R[Y_1, \ldots, Y_t]/(Y_1^{h_1} - x_1, \ldots, Y_t^{h_t} - x_t) \). This is a free finitely generated \( R \)-module and \( Y_1, \ldots, Y_t \) is a regular sequence in \( R' \). Set \( p = (Y_1, \ldots, Y_t)R' \). Then \( R'/p = R/(x_1, \ldots, x_t) \) is a regular domain, so \( p \) is a prime ideal, and for any prime ideal \( q \) in \( R' \) containing \( p \), \( R'_q \) is a regular local ring. By construction, \( I_H R' \) is contained in \( (Y_1, \ldots, Y_t)^h = p^h \). As \( R'_p \) is a regular local ring, \( p^h R'_p \) is integrally closed, and as \( R' \) is finitely generated over a locally formally equidimensional (regular) ring, \( R'_q \) is locally formally equidimensional for every prime ideal \( q \) containing \( p \). By a theorem of Ratliff, from [17], since \( p \) is generated by a regular sequence, the integral closure of \( p^h R'_p \)
has no embedded prime ideals. It follows that the integral closure of $p^h R_q'$ is $p^h R_p' \cap R_q'$. As $R_q'$ is a regular domain and $p$ is generated by a regular sequence, $p^h R_p' \cap R_q' = p^h R_q'$. It follows that $p^h R_p' \cap R' = p^h$ is the integral closure of $p^h$. Hence $\Gamma_H \subseteq p^h \cap R = p^h \cap R$, and by freeness of $R'$ over $R$, the last ideal is exactly $(\mathbb{Z}^\mathbb{N} | \sum h_i e_i \geq h)$, which finishes the proof.

3. Rees valuations of (general) monomial ideals

Recall that the Rees valuations of a non-zero ideal in a Noetherian domain form a unique minimal set $\mathcal{RV}(I)$ of finitely many normalized valuations such that for all positive integers $n$, $\Gamma^n = \{ r \in R \mid v(r) \geq nv(I) \text{ for all } v \in \mathcal{RV}(I) \}$.

In an arbitrary Noetherian domain, for arbitrary ideals $I$ and $J$, $\mathcal{RV}(I) \cup \mathcal{RV}(J) \subseteq \mathcal{RV}(IJ)$, and equality holds in two-dimensional regular domains. (This has appeared in the literature in several places, see for example Muhly-Sakuma [16], or the Rees valuations chapter in the upcoming book [20].)

We will prove that the Rees valuations of an ideal generated by monomials in a regular system of parameters are especially nice.

**Definition 3.1:** Let $R$ be a regular domain, and let $x_1, \ldots, x_d$ be a generalized regular system of parameters. A valuation $v$ on the field of fractions of $R$ is said to be monomial on $x_1, \ldots, x_d$ if for some $i_1, \ldots, i_s \in \{1, \ldots, d\}$, for any polynomial $f = \sum c_\nu x_{i_1}^{\nu_1} \cdots x_{i_s}^{\nu_s} \in R$ with all $c_\nu$ either 0 or not in $(x_{i_1}, \ldots, x_{i_s})$, $v(f) = \min\{v(x_\nu) \mid c_\nu \neq 0\}$. When the $x_i$ are understood from the context, we say that $v$ is monomial.

Observe that $v(f) = 0$ for any $f \notin (x_{i_1}, \ldots, x_{i_s})$. In particular $v(x_j) = v(1) = 0$ if $j \notin \{i_1, \ldots, i_s\}$.

**Proposition 3.2:** Let $R$ be a regular domain, let $x_1, \ldots, x_d$ be a generalized regular system of parameters, and let $a_1, \ldots, a_d$ be non-negative rational numbers, not all of them zero. Then there exists a unique valuation $v$ on the field of fractions $K = \mathbb{Q}(R)$ of $R$ that is
monomial on \( x_1, \ldots, x_d \), with \( v(x_i) = a_i \).

**Proof:** By reindexing we may assume that \( a_1 > 0, \ldots, a_s > 0, \quad a_{s+1} = \cdots = a_d = 0 \) for some \( s > 0 \), and we also may assume that all \( a_i \) are integers.

The uniqueness of \( v \) is immediate by Proposition 1.3. To prove the existence we may replace \( R \) by \( R_p \) (with \( p = (x_1, \ldots, x_s) \)) and assume that \( R \) is local. Let \( R' \) be the regular local ring obtained by adjoining a \( q^i \)-th root \( y_i \) of \( x_i \) to \( R \) \((i = 1, \ldots, s)\) and let \( n \) be the maximal ideal of \( R' \). Then the \( n \)-adic valuation \( w \) on \( L = \mathbb{Q}(R') \) is monomial in \( y_1, \ldots, y_s \) with \( w(y_i) = 1 \) for all \( i \). The restriction \( v := w|_K \) is a monomial valuation as desired. \( \square \)

**Corollary 3.3:** Let \( R \) be a regular domain, and let \( x_1, \ldots, x_d \) be a generalized regular system of parameters. Let \( I \) be an ideal generated by monomials in \( x_1, \ldots, x_d \). Then all the Rees valuations of \( I \) are monomial in \( x_1, \ldots, x_d \). Furthermore, if \( H_1, \ldots, H_\rho \) are the non-coordinate hyperplanes bounding \( NP(I) \), then the \( H_j \) are in one-to-one correspondence with the Rees valuations \( v_j \) of \( I \).

**Proof:** The Newton polyhedron \( NP(I) \) of \( I \) is the intersection of finitely many half-spaces in \( \mathbb{Q}^d \). Some of them are coordinate half-spaces \( \{ x_i \geq 0 \} \), each of the others is determined by a hyperplane \( H \) of the form \( h_1 x_1 + \cdots + h_d x_d = h \), with \( h_1, \ldots, h_d, h \) non-negative integers, \( h > 0 \), and \( \gcd(h_1, \ldots, h_d, h) = 1 \). This hyperplane corresponds to a valuation \( v_H \) that is monomial on \( x_1, \ldots, x_d \) and such that \( v_H(x_i) = h_i \). By Theorem 2.3, the integral closure of \( I \) is determined by these \( v_H \). Using \( NP(I^n) = n \cdot NP(I) \), we see that the integral closure of \( I^n \) is also determined by these \( v_H \). So each Rees valuation is one such \( v_H \). Suppose that the set of Rees valuations is a proper subset of the set of all the \( v_H \). Say one such \( v_H \) is not needed in the computation of the integral closures of powers of \( I \). Since the hyperplanes \( H \) were chosen to be irredundant, by omitting any one of them, we get a point \((e_1, \ldots, e_d) \in \mathbb{Q}^d_{\geq 0} \) which is on the unbounded side of all the hyperplanes bounding \( NP(I) \) other than \( H \), but is not on the unbounded side of \( H \). There exists \( m_1, \ldots, m_d \in \mathbb{N} \) and \( n > 0 \) such that for each \( i \), \( e_i = m_i/n \). Then by assumption, \( x_1^{m_1} \cdots x_d^{m_d} \in I^n \), but
Lemma 3.4: Let $R$ be a regular domain, and let $x_1, \ldots, x_d$ be a generalized regular system of parameters. Let $v$ be a discrete valuation that is monomial on $x_1, \ldots, x_d$, non-negative on $R$, and has value group contained in $\mathbb{Z}$. Then

$$v(J_{R_v}/R) = v(x_1 \cdots x_d) - \gcd(v(x_1)|i).$$

Proof: Since $v$ is monomial in the $x_i$, the center of $v$ on $R$ is contained in $m = (x_1, \ldots, x_d)$. By localizing, we may assume that $m$ is the only maximal ideal in $R$. Let $a_i = v(x_i)$. Without loss of generality $a_1 \geq a_2 \geq \cdots \geq a_d$, and let $s$ be the largest integer such that $a_s > 0$. As $v$ is monomial, if $s = 0$, then $v = 0$ and the lemma holds trivially. Thus we may assume that $s > 0$. If $s = 1$, necessarily $a_1 = \gcd(v(x_1)|i)$, and $v$ is $a_1$ times the $(x_1)$-grading. Then $R_v = R(x_1)$, $J_{R_v}/R = R_v$, $v(J_{R_v}/R) = 0 = v(x_1 \cdots x_d) - \gcd(v(x_1)|i)$. So the lemma holds in the case $s = 1$. We proceed by induction on $\sum_i a_i$. We may assume that $s > 1$. Let $S = R(x_1^{s_1}, \ldots, x_s^{s_s})$. Then $S$ is a regular ring contained in $R_v$, $x_1^{s_1}, \ldots, x_s^{s_s}, x_s, \ldots, x_d$ is a generalized regular system of parameters. For these elements in $S$, $v$ is still a monomial valuation, their $v$-values are non-negative integers, and the total sum of their $v$-values is strictly smaller than $\sum_i a_i$. Thus by induction,

$$v(J_{R_v}/S) = v\left(\frac{x_1}{x_s} \cdots \frac{x_{s-1}}{x_s} x_s \cdots x_d\right) - \gcd(v(x_1/x_s), \ldots, v(x_{s-1}/x_s), v(x_s), \ldots, v(x_d))$$

$$= v(x_1 \cdots x_d) - (s - 1)v(x_s) - \gcd(v(x_1), \ldots, v(x_d)).$$

As $R \subseteq S \subseteq R_v$ are all finitely generated algebras over $R$ that are regular rings and have the same field of fractions, by Lipman and Sathaye [14, page 201], $J_{R_v}/R = J_{S/R}J_{R_v}/S$. Clearly $J_{S/R}$ equals $x_s^{s-1}$, whence

$$v(J_{R_v}/R) = v(x_s^{s-1}) + v(x_1 \cdots x_d) - (s - 1)v(x_s) - \gcd(v(x_1), \ldots, v(x_d))$$

$$= v(x_1 \cdots x_m) - \gcd(v(x_1), \ldots, v(x_d)).$$

The following is a local version of Howald [5, Lemma 1]. Howald’s proof relies on the existence of a log resolution.
4. Adjoints of (general) monomial ideals

A proof similar to the proof of Theorem 2.3 shows that the adjoint of a (general) monomial ideal is monomial. This generalizes Howald’s result [5].

Theorem 4.1: Let $R$ be a regular domain, and let $x_1, \ldots, x_d$ be a generalized regular system of parameters. Let $I$ be an ideal generated by monomials in $x_1, \ldots, x_d$. Then for all $n \geq 1$,

$$\text{adj}(I^n) = \bigcap_v \left( \{ x^\underline{e} \mid v(x^\underline{e}) \geq v(I^n) - v(x_1 \cdots x_d) + 1 \} \right)$$

$$= \bigcap_v \left( \{ x^\underline{e} \mid v(x^\underline{e}) \geq v(I^n) - v(J_{R_v/R}) \} \right)$$

$$= \left( \{ x^\underline{e} : \underline{e} \in \mathbb{N}^d \text{ and } e + (1, \ldots, 1) \in \text{NP}^\circ(I^n) \} \right),$$

as $v$ varies over the (normalized) Rees valuations of $I$. In particular, the adjoint is also generated by monomials.

Proof: As $I^n$ is monomial and as the Rees valuations of $I^n$ are contained in the set of Rees valuations of $I$, it suffices to prove the theorem for $n = 1$. By Corollary 3.3 and by Lemma 3.4, the second and third equalities hold. So it suffices to prove that $\text{adj} I$ equals the other three expressions (when $n = 1$).

First we prove that $x^\underline{e} \in \text{adj}(I)$ whenever $\underline{e} \in \mathbb{N}^d$ with $\underline{e} + (1, \ldots, 1) \in \text{NP}^\circ(I)$. Let $v$ be a valuation as in the definition of $\text{adj}(I)$. As $(x_1 \cdots x_d x^\underline{e})^n \in I^{n+1}$ for some positive integer $n$, $v(x_1 \cdots x_d x^\underline{e}) > v(I)$. As $v$ is normalized, $v(x^\underline{e}) \geq v(I) - v(x_1 \cdots x_d) + 1$. By Lemma 1.2, $v(J_{R_v/R}) \geq v(x_1 \cdots x_d) - 1$, so that $v(x^\underline{e}) \geq v(I) - v(J_{R_v/R})$. As $v$ was arbitrary, this proves that $\{ x^\underline{e} : \underline{e} \in \mathbb{N}^d, \underline{e} + (1, \ldots, 1) \in \text{NP}^\circ(I) \} \subset \text{adj} I$. It remains to prove the other inclusion.

Let $S$ be the set of bounding hyperplanes of $\text{NP}(I)$ that are not coordinate hyperplanes. For each $H \in S$, if an equation for $H$ is $h_1 X_1 + \cdots + h_d X_d = h$ with $h_i \in \mathbb{N}$ and $h \in \mathbb{N}_{>0}$, define $I_H = (x^\underline{e} : \underline{e} \in \mathbb{N}^d, \sum_i h_i e_i \geq h)$. By the definition of Newton polyhedrons, $I \subseteq I_H$. 

Adjoints of ideals
By possibly reindexing, without loss of generality \( h_1, \ldots, h_t > 0 \) and \( h_{t+1} = \cdots = h_d = 0 \). By Proposition 3.2 there exists a monomial valuation \( \nu_H \) on \( Q(R) \) defined by
\[
\nu_H(x_i) = h_i.
\]
By construction, \( \nu_H(I) \geq \nu_H(I_H) > h \) (even equalities hold), and \( \text{adj}(I_H) \subseteq \{ r \in R \mid \nu_H(r) \geq \nu_H(I_H) - \nu_H(J_{R+H}/R) \} \). By the properties of \( \nu_H \), the last ideal is generated by monomials in the \( x_i \). By Lemma 3.4, \( \nu_H(J_{R+H}/R) = \nu_H(x_1 \cdots x_d) - 1 \), so that
\[
\text{adj}(I_H) \subseteq \bigcap_{H \in S} \text{adj}(I_H) \subseteq \bigcap_{H \in S} \left( \{ x^e \mid e \in \mathbb{N}^d, e \cdot (1, \ldots, 1) \in \text{NP} \circ (I) \} \right).
\]

This theorem allows to address the subadditivity problem for monomial ideals:

**Corollary 4.2:** Let \( I, J \subseteq R \) be ideals generated by monomials in the generalized regular system of parameters \( x_1, \ldots, x_d \). Then
\[
\text{adj}(IJ) \subseteq \text{adj}(I) \cdot \text{adj}(J).
\]

**Proof:** Let \( x^a \in \text{adj}(IJ) \) be a monomial. By Theorem 4.1, \( a + (1, \ldots, 1) \in \text{NP} \circ (I \cdot J) \). As \( \text{NP} \circ (IJ) \subseteq \text{NP} \circ (I) + \text{NP} \circ (J) \), there exist \( b \in \text{NP} \circ (I) \) and \( c \in \text{NP} \circ (J) \) with \( a + (1, \ldots, 1) = b + c \). Set \( f = (f_1, \ldots, f_d) \) and \( g = (g_1, \ldots, g_d) \) with \( f_i = [b_i] - 1 \) and \( g_i = [c_i] \). Then \( x^f \) and \( x^g \) are monomials with \( x^{f+g} = x^a \), and furthermore
\[
\begin{align*}
\underline{f} + (1, \ldots, 1) & \in b + \mathbb{Q}_{\geq 0}^d \subseteq \text{NP} \circ (I), \\
\underline{g} + (1, \ldots, 1) & \in c + \mathbb{Q}_{\geq 0}^d \subseteq \text{NP} \circ (J),
\end{align*}
\]
implying by Theorem 4.1 that $x^2 \in \text{adj}(I)$ and $x^2 \in \text{adj}(J)$.

From the proof of Theorem 4.1, it is clear that the Rees valuations of the adjoint depend on the Rees valuations of the original ideal. The number of Rees valuations of $I$ need not be an upper bound on the number of Rees valuations of $\text{adj}(I)$, and there is in general no overlap between the set of Rees valuations of $I$ and the set of Rees valuations of $\text{adj} I$.

**Example:** Let $R$ be a regular local ring with regular system of parameters $x, y$. Let $I$ be the integral closure of $(x^5, y^7)$. Then by the structure theorem, $I$ has only one Rees valuation, and $I = (x^5, x^4y^2, x^3y^3, x^2y^5, xy^6, y^7)$. By [7], by [5], or by Theorem 4.1, \( \text{adj}(I) = (x^4, x^3y, x^2y^2, xy^4, y^5) \), which is not the integral closure of \((x^4, y^5)\). Thus \( \text{adj}(I) \) has more than one Rees valuation. In fact, it has two Rees valuations, both of which are monomial and neither of which is equivalent to the Rees valuation of $I$: $v_1(x) = 1 = v_1(y), v_1(\text{adj}(I)) = 4$, and $v_2(x) = 3, v_2(y) = 2, v_2(\text{adj}(I)) = 10$.

Nevertheless, the one Rees valuation of $I$ still determines the adjoints of all the powers of $I$.

### 5. Adjoints of ideals and Rees valuations

In this section we characterize those ideals $I$ for which $\text{adj}(I^n)$ is determined by the Rees valuations of $I$ for all $n$. In the last section we have seen that this is the case for monomial ideals. That the Rees valuations of an ideal $I$ should play a crucial role in determining the adjoint of $I$ in general is also implied by the following result:

**Proposition 5.1:** Let $I$ be an ideal in a regular domain $R$, and let $\mathcal{V}$ be a finite set of valuations on the field of fractions of $R$ such that for all $n \in \mathbb{N}$,

$$\text{adj} I = \bigcap_{v \in \mathcal{V}} \{ r \in R | v(r) \geq v(I) - v(J_{R_v/R}) \}.$$ 

Then $\mathcal{V}$ contains the Rees valuations of $I$. 
Proof: Assume that there exist some Rees valuations of $I$ not contained in $V$. By the defining property of Rees valuations there exist a non-negative integer $n$ and an element $r \in R$ with

1. $v(r) \geq n \cdot v(I)$ for all $v \in V$.
2. $r \notin I^n$.

Let $w$ be a Rees valuation of $I$ with $w(r) \leq n \cdot w(I) - 1$. Assume that $I$ is $l$-generated and let $t \geq l \cdot w(I)$. Then

$$w(r^t) = t \cdot w(r) < (nt - l + 1)w(I),$$

hence

$$r^t \notin I^{nt-l+1}.$$

On the other hand,

$$v(r^t) \geq nt \cdot v(I) \geq nt \cdot v(I) - v(J_{R_v/I}) \quad \text{for all } v \in V,$$

implying that

$$r^t \in \text{adj}(I^{nt}) \subseteq I^{nt-l+1}$$

by [12], (1.4.1), a contradiction. □

It is not true in general that the set of Rees valuations determines the adjoint of an arbitrary ideal:

Example: Let $(R,\mathfrak{m})$ be a $d$-dimensional regular local ring, with $d > 2$, and let $\mathfrak{p}$ be a prime ideal in $R$ of height $h \in \{2, \ldots, d-1\}$ generated by a regular sequence. Then the $\mathfrak{p}$-adic valuation $v_\mathfrak{p}$ is the only Rees valuation of $\mathfrak{p}$. If $v_\mathfrak{p}$ defined $\text{adj}(\mathfrak{p}^n)$ in the sense that

$$\text{adj}(\mathfrak{p}^n) = \{r \in R \mid v_\mathfrak{p}(r) \geq nv_\mathfrak{p}(\mathfrak{p}) - v_\mathfrak{p}(J_{R_\mathfrak{p}/R})\} \quad \text{for all } n,$$

then, as $v_\mathfrak{p}(\mathfrak{p}) = 1$ and $J_{R_\mathfrak{p}/R} = \mathfrak{p}^{h-1}R_\mathfrak{p}$, it follows that

$$\text{adj}(\mathfrak{p}^{h-1}) = \{r \in R \mid v_\mathfrak{p}(r) \geq 0\} = R.$$
Adjoints of ideals

However, if \( p \) is generated by elements in \( \mathfrak{m}^e \), where \( e \geq d/(h - 1) \), and if \( v \) denotes the \( \mathfrak{m} \)-adic valuation, then

\[
\text{adj}(p^{h-1}) \subseteq \{ r \in R \mid v(r) \geq v(p^{h-1}) - v(J_{R_e/R}) \} \subseteq \{ r \in R \mid v(r) \geq d - (d - 1) \} \subseteq \mathfrak{m},
\]

which is a contradiction. A concrete example of this is \( R = k[[X, Y, Z]] \) with the prime ideal \( p = (X^4 - Z^3, Y^3 - X^2Z) \), which defines the monomial curve \((t^9, t^{10}, t^{12})\).

The following is a geometric reformulation of [18], see also [2], 2.3 or [13], 1.4:

**Remark:** Let \( R \) be a regular domain and let \( I \subseteq R \) be an ideal of \( R \). Let \( Y = \text{Spec}(R) \), \( P = R[IT] \), the Rees ring of \( I \) and let \( \mathcal{P} \) be its normalization and \( \varphi : X = \text{Proj}(\mathcal{P}) \rightarrow Y \) the induced scheme. Then \( X/Y \) is essentially of finite type by [14], p. 200 (see also [20, 9.2.3], for details). Thus \( \varphi \) is a projective, birational morphism, \( X \) is a normal, Noetherian scheme and \( IO_X \) is an invertible ideal. Let \( \mathfrak{P}_1, \ldots, \mathfrak{P}_r \) be the irreducible components of the vanishing set \( \mathfrak{V}(IO_X) \) of \( IO_X \) (i.e. those points \( x \) of \( X \) of codimension 1 such that \( IO_{X,x} \) is a proper ideal of \( O_{X,x} \)). Then \( O_{X,\mathfrak{P}_i} \) is a discrete valuation ring (with field of fractions \( K = Q(R) \)) and the corresponding valuations \( v_1, \ldots, v_r \) are exactly the Rees valuations of \( I \).

If \((R, \mathfrak{m})\) is local and \( I \) is \( \mathfrak{m} \)-primary, the Rees valuations correspond to the irreducible components of the closed fibre \( \varphi^{-1}(\mathfrak{m}) \) which in this case is a \((\dim(R) - 1)\)-dimensional projective scheme (in general neither reduced nor irreducible).

Let \( f : Z \rightarrow Y \) be birational and of finite type. Then the Jacobian ideal \( \mathfrak{d}_{Z/Y} \subseteq O_Z \) is well-defined (being locally the 0\(^{th}\)-Fitting ideal of the relative Kähler differentials). If in addition \( Z \) is normal, then

\[
\omega_{Z/Y} := O_Z : \mathfrak{d}_{Z/Y} = \mathcal{H}om_Z(\mathfrak{d}_{Z/Y}, O_Z)
\]

is a canonical dualizing sheaf for \( f \) with

\[
O_Z \subseteq \omega_{Z/Y} \subseteq M_Z,
\]
where $M_Z$ denotes the constant sheaf of meromorphic functions on $Z$. If

$$g : Z' \rightarrow Z$$

is another birational morphism and if $g$ is proper and $Z'$ is normal as well, then

$$g_*\omega_{Z'/Y} \subseteq \omega_{Z/Y}$$

(cf. [14, 2.3] and [15, §4]).

**Theorem 5.2:** Let $R$ be a regular domain and let $I \subseteq R$ be a non-trivial ideal. Furthermore let $Y = \text{Spec}(R)$ and $\varphi : X \rightarrow Y$ be the normalized blow-up of $I$. Then the following are equivalent:

1. $\text{adj}(I^n) = \bigcap_{v \in \mathcal{V}(I)} \{ r \in R \mid v(r) \geq n \cdot v(I) - v(J_{R^+}/I) \}$ for all positive integers $n$.
2. If $Z$ is a normal scheme and $\pi : Z \rightarrow X$ is proper and birational, then
   $$\pi_*\omega_{Z/Y} = \omega_{X/Y}.$$

**Remark:** If in the situation of 5.2(2) the scheme $X$ is Cohen–Macaulay as well, then $X$ has pseudo-rational singularities only ([15, §4]).

**Remark:** In the situation of 5.2(1) the set $\mathcal{V}(I)$ is the unique smallest set of valuations defining $\text{adj}(I^n)$ in view of Proposition 5.1.

**Proof of Theorem 5.2:** If $f : Z \rightarrow Y$ is proper and birational with $Z$ normal and $I/I_O$ invertible, we set

$$\text{adj}(I^n) = H^0(Z, I^n\omega_{Z/Y}) \ (\subseteq R).$$

Then $\text{adj}(I^n) = \bigcap \text{adj}(I^n)$ by [12], where $f : Z \rightarrow Y$ varies over all such morphisms. By the universal properties of blow-up and normalization, any such $f$ factors as

$$Z \xrightarrow{\pi} X \xrightarrow{\varphi} Y,$$

As $\pi_*\omega_{Z/Y} \subseteq \omega_{X/Y}$, and as $I/I_O$ is invertible, this implies by the projection formula
\[ H^0(Z, I^n \omega_{Z/Y}) = H^0(X, \pi_* I^n \omega_{Z/Y}) \]
= \[ H^0(X, I^n \pi_* \omega_{Z/Y}) \]
\subseteq \[ H^0(X, I^n \omega_{X/Y}) \],
and therefore
\[(\ast) \quad \text{adj}_Z(I^n) \subseteq \text{adj}_X(I^n) \quad \text{for all positive integers } n \]
for any such \( f : Z \to Y \).

As \( \omega_{X/Y} \) is reflexive by \([14, \text{p. 203}]\), and as \( I\mathcal{O}_X \) is invertible, \( I^n \omega_{X/Y} \) is a reflexive coherent subsheaf of the sheaf of meromorphic functions of \( X \), and therefore we have
\[ H^0(X, I^n \omega_{X/Y}) = \bigcap_{x \in X : \text{ht}(x) = 1} (I^n \omega_{X/Y})_x. \]

For \( x \in X \) with \( \varphi(x) \notin \mathfrak{V}(I) \), the set of primes containing \( I \), we have
\[ I\mathcal{O}_{X,x} = \mathcal{O}_{X,x}, \]
\[ \omega_{X/Y,x} = \mathcal{O}_{X,x}, \]
as \( \varphi \) is an isomorphism away from \( \mathfrak{V}(I) \). Those \( x \in X \) with \( \text{ht}(x) = 1 \) and \( \varphi(x) \in \mathfrak{V}(I) \) correspond to the Rees valuations of \( I \), and thus
\[
\text{adj}_X(I^n) = H^0(X, I^n \omega_{X/Y})
= \bigcap_{x \in X : \text{ht}(x) = 1} (I^n \omega_{X/Y})_x
= \bigcap_{x \in X : \text{ht}(x) = 1, \varphi(x) \notin \mathfrak{V}(I)} (I^n \omega_{X/Y})_x \cap \bigcap_{x \in X : \text{ht}(x) = 1, \varphi(x) \in \mathfrak{V}(I)} \mathcal{O}_{X,x}
\supseteq \bigcap_{v \in \mathfrak{V}(I)} \{ r \in R : v(r) \geq n \cdot v(I) - v(J_{R_{R/R}}) \},
\]
where we also use, that \( \omega_{R_{R/R}} \) is an invertible fractional ideal with inverse \( J_{R_{R/R}} \). As \( \pi_* \omega_{X/Y} = \mathcal{O}_X \) by \([15, \S 4]\), hence \( H^0(X, \omega_{X/Y}) = R \), the converse inclusion is obvious:
\[
\text{adj}_X(I^n) = \bigcap_v \{ r \in K : v(r) \geq n \cdot v(I) - v(J_{R_{R/R}}) \} \cap R
\]
\[ \subseteq \bigcap_{v \in RV(I)} \{ r \in R : v(r) \geq n \cdot v(I) - v(J_{R_v/R}) \}, \]

and we conclude that

\[ \text{adj}_X(I^n) = \bigcap_{v \in RV(I)} \{ r \in R | v(r) \geq n \cdot v(I) - v(J_{R_v/R}) \}. \]

Thus (1) is equivalent to

\[ \text{adj}_X(I^n) = \text{adj}_Z(I^n) \quad \text{for all } n \in \mathbb{N} \]

for all \( f : Z \to Y \) as above.

First assume (2). This direction is implicit in [12], cf. [12], 1.3.2(b). Let \( f : Z \to Y \) be as above. By the assumptions we have trivially

\[ H^0(X, I^n \pi_* \omega_{Z/Y}) = H^0(X, I^n \omega_{X/Y}) \]

implying by the calculations preceeding (\( \ast \)) that \( \text{adj}_X(I^n) = \text{adj}_Z(I^n) \) for all positive integers \( n \). Thus (1) follows.

Conversely suppose that (1) holds, i.e., that \( \text{adj}(I^n) = \text{adj}_X(I^n) \) for all positive integers \( n \). Then by (\( \ast \)) we must have that the canonical inclusions

\[ H^0(X, I^n \pi_* \omega_{Z/Y}) = \text{adj}_Z(I^n) \hookrightarrow \text{adj}_X(I^n) = H^0(X, I^n \omega_{X/Y}) \]

are isomorphisms for all positive integers \( n \). If \( X' \) denotes the blow-up of \( I \) on \( Y \), then \( I \mathcal{O}_{X'} \) is a very ample invertible sheaf on \( X' \). As \( X/X' \) is finite, \( I \mathcal{O}_X \) is an ample invertible sheaf on \( X \), and thus the above isomorphisms imply that the canonical inclusion

\[ \pi_* \omega_{Z/Y} \hookrightarrow \omega_{X/Y} \]

is an isomorphism, i.e., that (2) holds.

For both conditions in the theorem some examples are known, as we show below.
Recall that two ideals $I, J \subseteq R$ are called projectively equivalent if there exist positive integers $i, j$ with $I^i = J^j$, cf. [2].

**Corollary 5.3:** Let $R$ be a regular domain, let $x_1, \ldots, x_d$ be a generalized regular system of parameters, and let $I$ be an ideal projectively equivalent to an ideal generated by monomials $x_1^{a_1}, \ldots, x_1^{a_s}$ in $x_1, \ldots, x_d$. Then $\text{adj}(I)$ is a monomial ideal in $x_1, \ldots, x_d$, determined by the Rees valuations of $I$, and the normalized blow-up of $I$ satisfies condition (2) of 5.2.

**Proof:** It remains to note that

$$\text{Proj}(R[It]) = \text{Proj}(R[I^it]) = \text{Proj}(R[It]).$$

Then the corollary follows from Theorem 4.1. \qed

By the work of Lipman and Teissier we also know (2) in some cases.

**Corollary 5.4:** Let $(R, m)$ be a two-dimensional regular domain. Then for any non-zero ideal $I$,

$$\text{adj}(I) = \bigcap_{v \in RV(I)} \{ r \in R \mid v(r) \geq v(I) - v(J_{Rv/R}) \}.$$

**Proof:** It remains to note that in the two-dimensional case the normalized blow-up of $I$ has pseudo-rational singularities only by [15], p. 103 and [11], 1.4. Thus condition (2) of 5.2 is satisfied. \qed

**Remark:** In the case of two-dimensional regular rings an elementary direct proof of 5.4 can be given as well: We may assume that $(R, m)$ is local with infinite residue field and that $I$ is $m$-primary. Then it follows from [6] and [7] (see also [12]) that for a generic $x \in m \setminus m^2$ the ideals $I$ and $\text{adj}(I)$ are contracted from $S := R[\frac{m}{x}]$ and that $\text{adj}(I)S = \frac{1}{x} \text{adj}(IS)$. From this 5.4 follows by an easy induction on the multiplicity $\text{mult}(I)$ of $I$.

With this line of argument we can also give an easy proof of subadditivity of adjoint ideals in the two-dimensional case. Again we may assume that $(R, m)$ is local with infinite
residue field, and that $I$ and $J$ are $m$-primary. For a generic $x \in m \setminus m^2$ we will have that $I$, $J$, $IJ$, $\operatorname{adj}(I)$, $\operatorname{adj}(J)$, $\operatorname{adj}(IJ)$ and $\operatorname{adj}(I) \operatorname{adj}(J)$ are contracted from $S = R[\frac{m}{x}]$.

Denoting by $I'$, resp. $J'$, the strict transforms of $I$, resp. $J$, we conclude by the above and by induction on $\text{mult}(I) + \text{mult}(J)$:

$$\operatorname{adj}(IJ) = \operatorname{adj}(IJ)S \cap R = \frac{1}{x} \operatorname{adj}(IJS) \cap R = x^{\operatorname{ord}(I)+\operatorname{ord}(J)-1} \operatorname{adj}(I'J') \cap R \subseteq x^{\operatorname{ord}(I)-1} \operatorname{adj}(I') \cdot x^{\operatorname{ord}(J)-1} \operatorname{adj}(J') \cap R = \operatorname{adj}(I) \operatorname{adj}(J)S \cap R = \operatorname{adj}(I) \operatorname{adj}(J).$$

Alternatively, the subadditivity result may be deduced from [13] and [12]. We note that Tagaki and Watanabe [22] proved subadditivity of adjoint ideals more generally, for two-dimensional log-terminal singularities. The argument given here does not extend to their situation.

Acknowledgements. We thank the referee for pointing out a crucial simplification.
